Job Market Paper

The Supply Side of Consumer Debt Repayment (with Justin Katz and Claire Shi)

We study how lender responses to consumer biases affect credit card debt. Using account-level credit bureau data, we document a new fact: many consumers make near-minimum credit card repayments while also overpaying lower-interest installment debt. We estimate an empirical model in which credit card lenders optimally set minimum payments given this behavior. Because some

liquid consumers pay near the minimum on their credit cards, lenders lower minimums to slow repayment, increasing high-interest debt balances and interest revenue. Our model implies that this lender response increases credit card debt by between $35 and $48 billion. This finding illustrates how optimizing lenders can amplify the effects of consumer biases in equilibrium.

Working Papers

Revenue-Based Financing (with Claire Shi and Rowan Clarke), *R&R at Review of Financial Studies*

We study revenue-based financing, an emerging capital source for small firms in low- and middle-income countries. Using transaction-level data from a South African payment platform, we show firms that take financing process 16% less revenue through the platform than observably similar non-takers after eight months, slowing repayment. Two natural experiments show this reflects moral hazard from firms diverting revenue and adverse selection. Repayment improves when firms use the platform's other services (e.g., inventory management tools), and screening improves with longer histories and repeat financing. Our results highlight the frictions with flexible repayment models in developing economies, and how providers mitigate them.

Who Borrows on Credit Cards? The Economic and Social Determinants of Consumer Debt (with Trevor J. Bakker and Claire Shi)

Using linked credit bureau and Census data, we show that credit card debt is highly persistent, insensitive to income changes, and negatively predicts future income growth. Standard rational or behavioral consumption-smoothing models cannot generate these facts without heterogeneous types. We study the sources of this heterogeneity and show that it is shaped in part by the behavior of one's parents. Exploiting variation in the age of children at parental separation, we document a causal effect of parental exposure. Parents transmit specific repayment behaviors, such as overpaying installment debt while revolving credit card debt, as well as broader cultural attitudes. Our findings suggest that learned norms are an important determinant of household borrowing.

Gambling for Goals (with Costas Arkolakis, Spencer Y. Kwon, Claire Shi, and Hyunjoo Yang)

Young adults in advanced economies have grown more pessimistic about their economic prospects in recent years. At the same time, gambling-like financial activities have proliferated. We link these trends through a Friedman-Savage (1948) motive: when life goals such as homeownership or marriage seem out of reach, individuals turn to financial gambles. We test this theory using an original survey combined with millions of linked records from Korea's leading credit bureau, telecom provider, and credit card issuer. Consistent with the theory, individuals who place greater importance on hard-to-reach goals take more risk, and the form of risk they take varies systematically with their distance from those goals. Within individuals, cryptocurrency app usage rises during unemployment and falls after winning the right to purchase price-regulated housing through a lottery. A calibration shows how hard-to-reach goals lead households to act more aggressively on their beliefs, amplifying the consequences of overoptimism.

Behavioral Cross-Selling: Evidence from Retail Credit Cards (with Sarah E. Robinson and Claire Shi)

Why do some non-financial firms rely on revenue from consumer financial products? At several large U.S. retailers, direct revenues from credit card partnerships exceed total operating income. This paper proposes a theory of behavioral cross-selling, in which firms use their access to customers to cross-sell products that capitalize on behavioral biases, such as inattention or forgetfulness. We test our theory in the retail credit card market using data from a major credit bureau. Although retail cards account for only 17% of balances in our sample, they generate 45% of missed minimum payments, triggering late fees. Liquidity constraints cannot fully explain missed minimums: among individuals with multiple cards, nearly half of missed payments on retail cards could have been avoided by reallocating excess payments from other cards. Consistent with the theory, firms in locations with more avoidable missed payments are more likely to offer retail cards and provide larger sign-up incentives. We discuss how behavioral cross-selling can help explain practices in industries such as airlines, auto dealerships, tax preparation services, and sports entertainment.

Competition in Generative AI: Evidence from Consumer Demand (with Mark Egan, Claire Shi, and Vincent Yao)

How competitive will the market for generative AI be as it matures? Using novel transaction-level credit and debit card data covering 174 million consumers and 114 billion transactions, we study the adoption of paid services and the demand-side foundations of competition in this market. As of April 2026, approximately 2.9% of U.S. consumers pay for at least one major generative AI service, with adoption highest among younger and higher-income consumers. Nearly all of these paid users subscribe to basic plans that cost $30 or less per month. Three patterns suggest limited differentiation and low switching costs. First, although multihoming is common, it has declined as providers' capabilities have expanded. Second, annual customer retention rates range from 20% to 45% across major AI providers, lower than those for many other subscription products. Third, switching rises around major model releases. Motivated by these findings, we develop and estimate a structural model of AI service demand and supply that reveals strong competitive pressure. Consumers are highly price sensitive, have much weaker preferences for particular providers than for AI overall, and view AI services as increasingly close substitutes. Our results suggest that, absent a substantial increase in AI model quality differentiation, growing substitutability among services will constrain providers' pricing power and allow consumers to capture a large share of the surplus generated by these services.
